

ERYND · 2 — Production, your own SaaS server

Same core idea, hardened to serve many paying customers safely and 24/7 — on infrastructure **you own**. New pieces are marked NEW.

You / users

Frontend

Backend

Database

Outside services

YOUR CUSTOMERS

Many users, any browser

They visit **app.yourcompany.com** — a real web address, not localhost.

▼ secure connection (https)

FRONT DOOR NEW

Reverse proxy + HTTPS

The single guarded entrance (Nginx/Caddy). Handles the padlock/encryption, blocks abuse, routes traffic.

routes to your two running apps

FRONTEND (SERVED AS FILES)

The interface

Same React app, pre-built and served fast to everyone.

BACKEND · SEVERAL COPIES NEW

The brain (scaled)

Multiple identical copies at once, so many users are served smoothly and one crash doesn't down the app.

the backend relies on a fuller support cast

DATABASE UPGRADED

PostgreSQL

A professional database (replaces the single file).
Keeps each customer's data separate and safe.
Built as a one-line swap.

ACCOUNTS & BILLING NEW

Login + subscriptions

Sign-up, log-in, "who is this and what plan", and payments (Stripe). Replaces today's single shared token.

BACKGROUND WORKERS NEW

Always-on jobs + queue

The "watching" engine — continuously pulls mentions and runs alerts on a schedule, separate from live chats.

and these outside services, over the internet

OUTSIDE · AI

Claude (Anthropic)

The intelligence, as today — or your future Apify-based agent, swappable without touching the rest.

OUTSIDE · DATA SOURCES NEW

Apify / social & news

Where real mentions come from instead of demo data.

SAFETY NET NEW

Backups + monitoring

Automatic backups, error alerts and health dashboards so you sleep at night.

NEW IN PRODUCTION

WHY A SAAS NEEDS IT

Front door (proxy + HTTPS)

A public, encrypted, single entrance with the padlock — required the moment strangers use your app.

Several backend copies

Handles many users at once and stays up if one copy crashes. This is "scaling."

PostgreSQL

The single-file database suits one person, not hundreds. Postgres is the proven choice — and the swap is trivial by design.

Accounts & billing

Real sign-up/login, keeping each customer's data private, and charging subscriptions.

Background workers + queue

Monitoring runs continuously on a schedule, not only when someone is chatting.

Real data sources (Apify)

Live mentions from social/news replace the demo dataset.

Backups & monitoring

Protects against data loss and warns you when something breaks before customers notice.

The reassuring part: the shape barely changes. **Frontend** → **Backend** → **Database + AI** is identical in both pictures. Production is mostly *adding a support cast* around the same core — and the two biggest jumps (Postgres, and the Apify agent) were designed in from day one as near one-line changes. Everything except the two cloud "outside services" runs on a server **you own**.
